

1 Exercise 1: Retrieving information for the protein TMM25_HUMAN

This code below does the following:

1. Get the sequence (`getSequence`)
2. Split by lines (`stream.splitlines()`)
3. Trim all carriage returns (`process`)
4. Get the id (`getid`)
5. Get signal (`get_signal_range`)
6. Get sequence (`get_aa_seq`)

The output is:

Currently processing the sequence with the name UNIPROT:TMM25_HUMAN
There is a signal peptide ending at position 26
The signal peptide looks like this: MALPPGPAALRHRTLLLLPALLSSGWG

The code:

```
def exercise_1(query_seq: str):
    def process(txt):
        """make it a bit cleaner"""
        # return [[s.strip() for s in line.split(" ") if s] for line in txt]
        data = []
        for line in txt:
            data.append([s.strip() for s in line.split(" ") if s])
        return data

    def getid(lines):
        for line in lines:
            if line[0] == "ID":
                return line[1]

    def get_aa_seq(lines: list[list[str]], signal_start: int, signal_end: int):
        aa_start = 0
        aa_end = 0
        for lineno, line in enumerate(lines):
            if line[0] == "SQ":
                # everything from SQ to end is protein sequence
                aa_start = lineno
            if line[0] == "//":
                aa_end = lineno

        aa = "".join(
            [item for sublist in lines[aa_start + 1 : aa_end] for item in sublist]
```

```

    )
    # minus 1, lists start at 0
    return aa[sig_start - 1 : sig_end]

def get_signal_range(lines: list[list[str]]) -> tuple[int, int]:
    for line in lines:
        if line[0] == "FT" and line[1] == "SIGNAL":
            r = line[2]
            [s, e] = r.split("..")
            return int(s), int(e)

    raise RuntimeError("Did not find signal range")

stream = getSequence(query_seq, format="txt")
txt = stream.splitlines()
lines = process(txt)
seqid = getid(lines)
sig_start, sig_end = get_signal_range(lines)
aa_seq = get_aa_seq(lines, sig_start, sig_end)

print(f"Currently processing the sequence with the name UNIPROT:{seqid}")
print(f"There is a signal peptide ending at position {sig_end}")
print(f"The signal peptide looks like this: {aa_seq}")

```

2 Exercise 2: Retrieve and process information about multiple members of the same protein family

Here is the commented code to fetch the D amino acid oxidases that have been reviewed and the species they occur in.

After running the code, it found 11 exemplars in E. coli.

```

def exercise_2():
    # list of `Sequence` class with useful information and methods about a given sequence
    seqs = []

    # list of ids representing an organism that contains DAO and has been reviewed
    names = searchSequences("family:DAO AND reviewed:true")

    # count of occurrences of E. Coli DOA protein
    cnt = 0

    # get each sequence data from uniprot
    for name in names:
        seq = getSequence(name)
        # add to list for writing to file later
        seqs.append(seq)

```

```

# ensure start of sequence is found in data
start_index = seq.annot.find("OS=")

# it's found!
if start_index != -1:
    end_index = seq.annot.find("=", start_index + 3)

# ensure end of sequence is found in data
if end_index == -1:
    end_index = len(seq.annot)

# python slicing to get annotation data
species = seq.annot[start_index + 3 : end_index]

# print name of seq
print(seq.name, "\t", species)

# if it's E. Coli, increment count
if species.startswith("Escherichia coli"):
    cnt = cnt + 1
else:
    print(seq.name, "\tno species")

# write to file
writeFastaFile("dao.fa", seqs)

if cnt > 0:
    print("Found %d exemplars in E. coli" % cnt)

```

3 Exercise 3: Processing the FASTA format

The fasta file format contains genome sequence data. Format is a (>) followed by a description of the sequence (on the same line). The following line is the sequence. Multiple sequences can be included in a single file. Empty lines are ignored.

The example provided will fail because the second sequence has leading white space before the (>) character.

4 Exercise 4: Find two putative homologs to *your* D-amino-acid oxidase

4.1 Part A

1. My sequence number: 83. Sequence: sp|B1JGH2|MNMC_YERPYP
2. Sequence 1: sp|A4TM73|MNMC_YERPP. Percent: 1.0
3. Sequence 2: sp|A9R7V8|MNMC_YERPG. Percent: 1.0

4.2 Part B

Here is my code.

```
def exercise_4(my_sequence_number, seqs, sub_matrix):
    """
    find two putative (assumed to be related) homologous (proteins sharing common ancestry)
    """

    # a bunch of temp vars to track the closest matches
    best1 = 0
    idx1 = 0
    best2 = 0
    idx2 = 0
    total = len(seqs)

    for idx in range(total):
        # Progress UI
        print(f"Running for {idx} / {total}")
        # do not match against itself - not a putative homolog
        if idx != my_sequence_number:
            seq = seqs[idx]
            # align my sequence and the current one and score
            aln = align(seqs[my_sequence_number], seq, sub_matrix, -7)
            percent = scoreAlignment(aln) / aln.alignlen

            # if it is the best, save it.
            # this means the current best is demoted the second best
            if best1 < percent:
                best2 = best1
                idx2 = idx1
                best1 = percent
                idx1 = idx

            # new second best, replace existing one
            elif best2 < percent:
                best2 = percent
                idx2 = idx

    print(f"Best match index is {idx1}. Sequence is:\n\n{seqs[idx1]}")
    print(f"\n\nSecond best match index is {idx2}. Sequence is:\n\n{seqs[idx2]}")
```

4.3 Part C

Links:

1. <https://www.uniprot.org/uniprotkb/B1JGH2/entry>
2. <https://www.uniprot.org/uniprotkb/A4TM73/entry>
3. <https://www.uniprot.org/uniprotkb/A9R7V8/entry>

All three sequences are for an identical protein. It is the (**mmC**) gene. One comes from *Yersinia pseudotuberculosis* (causes scarlet fever) and the other two from *Yersinia pestis* (causes the plague). These two organisms are closely related and it's not surprisingly they share a gene like (**mmC**).

It is involved in biosynthesis of 5-methylaminomethyl-2-thiouridine, in the wobble position in tRNA. The wobble position is the third position in the anticodon and has a high amount of flexibility (it can "wobble") when pairing during translation. This means it is involved in recognising codons during translation.

5 Exercise 5: Determine the consensus sequence for the D-amino-acid oxidase MSA

Here is my code.

```
def exercise_5(aln: Alignment):
    cols = len(aln[0])
    con_seq = ""
    # loop each col and grab the next char
    for i in range(cols):
        char = getConsensusForColumn(aln, i)
        # append it
        con_seq += char
    # return a Sequence instance
    return Sequence(con_seq, Protein_Alphabet, name='Consensus Sequence', gappy=True)
```

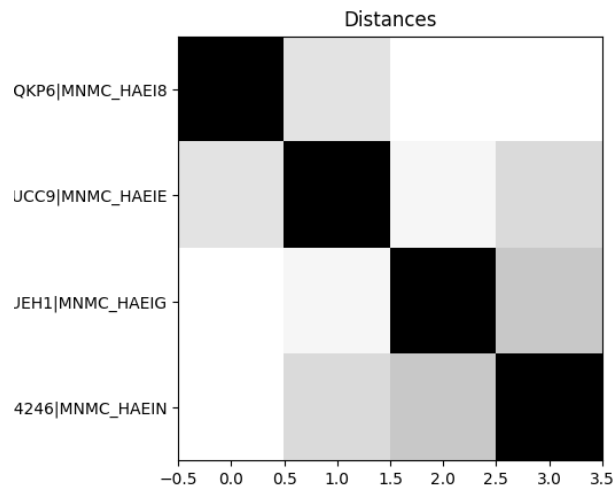

The sequence:

```
-----SIQPATL---EWNE---D---GTPVSRQFDDVYFSNDNGLE
ETRYVFLGGNGLPERWAEH-----RLFVIAETGFGTGLNFLALWQAF
RQFRPA-----LQRLHFISFEKFPLTRADLARAHQ-----

```

6 Exercise 6: Add the Poisson and Gamma distance metrics to ‘calcDistances’

Code:

```
def calcDistances(self, measure = 'fractional', a=1.0):
    """ omitted for brevity """
    # Now calculate the specified measure based on p
    p = D / L
    if measure == 'fractional':
        dist = D / L
    elif measure == 'poisson':
        # This is how you calculate poisson distance. Negative log of 1 - p dist
        dist = -numpy.log(1 - p)
    elif measure == "gamma":
        # assume a = 1 for alpha
        # can be 0.2 to 3.5 according to textbook
        # todo: make it a parameter?
        # todo: why can't I use math.gamma(p)?
        # It gives drastically different numbers.
        # I guess math.gamma is not a gamma DISTANCE but just the result of gamma function?
        a = 1
        dist = a * (((1 - p) ** (-1 / a)) - 1)
    else:
        raise RuntimeError('Not implemented: %s' % measure)
```

7 Exercise 7: Curate the MalS.fa dataset

Selected 31 sequences. Code:

```
import pandas as pd

def get_yeasts():
    """ Get a list of all the yeast species """
    df = pd.read_csv("Files_WS2/sugars.csv")
    return list(df["Yeast"])

def exercise_7():
    """
    Curate the MalS.fa dataset
    """

    # Get all yeast from sugars.csv
    yeasts = get_yeasts()

    mals = guide.readFastaFile('Files_WS2/MalS.fa', guide.Protein_Alphabet)
    cnt = 0
    select = []

    # traverse mals dataset
    for seq in mals:

        # we are only interested in yeast also in the sugars.csv list
        if seq.name in yeasts:

            # white space -> _
            new_name = (seq.name + "_" + seq.annot).replace(" ", "_")
            seq.name = new_name
            cnt += 1
            select.append(seq)

    guide.writeFastaFile('select.fa', select)
    print('Selected', cnt, 'sequences')
```

8 Exercise 8: Identify the consensus sequence for the MalS alignment

I put my fasta file into the ClustaW web interface, and this is the consensus sequence it gave me.

```

I wrote some code to verify the conserved residues match the figure in the paper.

```
voordeckers = [173, 231, 232, 233, 234, 294, 295, 324, 437]

def exercise_9():
    """
    This code print: YVGSLMQDE. This aligns with the figure 4 in the paper.
    """
    seq = "MVSMPN ... omitted for brevity ... NESA--"
    for a in voordeckers:
        print(seq[a-1], end="")
```

Should be "YVGSLMQDE" as per figure 4 in the paper. This looks correct for the isomaltose-like group.

- 173: Y
- 231-234: VGSL

- 294-295: MQ
- 324: D
- 437: E

· Sklu SAKL0C00176g	F	V	G	S	M	V	G	S	E

10 Exercise 10: Infer the phylogenetic relationships among select MalS proteins

```
def exercise_10():
    aln = guide.readClustalFile('exercise7.aln', guide.Protein_Alphabet)
    phy = guide.runUPGMA(aln, 'poisson')
    print(phy) # print so we can copy into jstree
    return phy
```

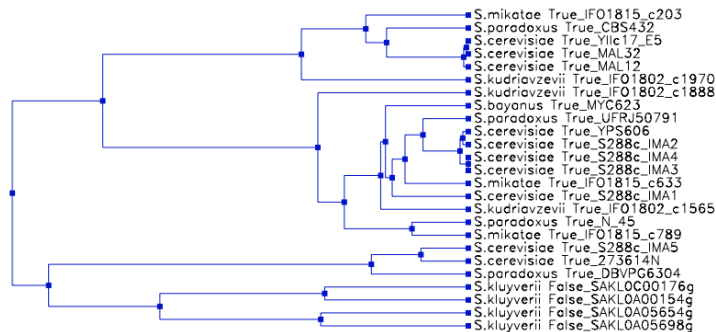

Here's the tree:

11 Exercise 11: Annotate your tree with metabolised sugars

Here is my code. I loop each sugar, then for each one, loop each yeast and update the labels with string replacement.

I found Melizitose can metabolize => 8 / 14 sugars. I visualized it.

This tree suggests that at some point in the past, there was a speciation event and *S.kluyverii* diverged from the other *Saccharomyces*. At this split, *S.kluyverii* underwent a mutation(s) in a gene(s) and became unable to metabolize Melizitose.

Code:

```
def exercise_11():
    """ Annotate tree with metabolized sugars """
    df = pd.read_csv("Files_WS2/sugars.csv")
    yeasts = list(df["Yeast"])
    aln = guide.readClustalFile('exercise7.aln', guide.Protein_Alphabet)
    phy = guide.runUPGMA(aln, 'poisson')
    df = df.set_index(df['Yeast'])

    for col_name in df.columns[1:]:
```
